

# LEWIS DOT STRUCTURES/DIAGRAMS

## Lewis Dot Structure/Diagram for an ATOM:

The Electron Configuration for a Nitrogen atom is  $[\text{He}] 2s^2 2p^3$

The Orbital Diagram for N is

Thus, the Valence Shell of N is  $2s^2 2p^3$  with a total of 5 Valence Electrons (= sum of exponents in the Valence Shell).

As easier way to determine the number of Valence Electrons is to look at the Group Number in the Periodic Table. N is in Group 5, which means it has 5 Valence Electrons.

So the Lewis Dot Structure/Diagram for N has 5 dots around the N atom. 2 dots are in a pair for  $2s^2$  and 3 dots are unpaired for  $2p^3$

*Try These!*

P	H
O	S
F	Cl

### Periodic Table with Group Numbers:

## Lewis Dot Structure/Diagram for a MOLECULE:

- 1) Count the number of Valence Electrons ( = Group Number) for each element.
- 2) Add these together for the **total Valence Electrons for the molecule** (even!)
  - a. If the molecule is a polyatomic ion:
    - i. Anions: for negative charges, add electrons to this **total**
    - ii. Cations: for positive charges, subtract electrons from this **total**
- 3) Make the least electro-negative atom the central atom.
  - a. Electronegativity decreases down a group and from right to left across a period; *Fr is the least electro-negative.*
  - b. *H and F can never be the central atom because they each need only one electron to complete their respective duplet and octet.*
  - c. *Halogens are rarely the central atom.*
- 4) Draw a skeletal structure. Write the rest of the atoms around the central atom, connecting each of them to the central atom with a **line**.
  - a. Each **line** indicates a **single bond**, which involves 2 Valence Electrons.
- 5) Complete the Octets of each of the outer atoms, by drawing 6 dots in 3 pairs around the element symbol (to be added to the 2 electrons accounted for by the **single bond** with the central atom).
  - a. 1<sup>st</sup> period element (H): Maximum 2 electrons (Duplet Rule).
- 6) Complete the Octet of the central atom by drawing dots (to be added to the 2 electrons for each **single bond** already drawn).
  - a. 2<sup>nd</sup> period elements: Maximum 8 electrons in outermost shell (Octet Rule).
    - i. Exceptions: *Be can have 4 electrons and B can have 6 electrons.*
  - b. 3<sup>rd</sup> period (and beyond) elements: Can have more than 8 electrons because of the empty 3d orbitals (Expanded Octet Rule).
    - i. *Al can have 6 or 8 electrons.*
    - ii. *P, Cl, Se, and Sb and can have 8 or 10 electrons.*
    - iii. *S, Br, I, and Xe can have 8, 10, or 12 electrons.*
- 7) Count the **sum of the electrons in the structure**
  - a. each dot = 1 electron; each **line** = 2 electrons
- 8) Compare this **sum from the structure** to the **total Valence Electrons** for the molecule (from Step 2). If these are equal, the structure is complete!
  - a. If the **sum of the electrons in the structure** is more that the **total Valence Electrons** of the molecule:
    - i. Erase one pair of electrons from both an outer atom and the central atom; make the bond between those a double bond. Then re-count the sum of the electrons in the structure.
    - ii. Repeat with another outer atom as necessary.
    - iii. If all possible double bonds have been formed and there are still more **electrons in the structure** than there should be, erase another pair of electrons from both an outer atom and the central atom; make the bond between these a triple bond. Then re-count.
    - iv. Repeat with another outer atom as necessary.
